

Two Advanced Diagnostic Technologies for China

1 Introduction

Diagnostics play a pivotal role in medicine: more precise diagnostics allow more effective treatments. At the Webpage of the Chinese National Development and Reform Commission (NDRC) we find this text: “We should strengthen cooperation with neighboring countries on epidemic information sharing, the exchange of prevention and treatment technologies and the training of medical professionals, and improve our capability to jointly address public health emergencies. We will provide medical assistance and emergency medical aid to relevant countries, and carry out practical cooperation in maternal and child health, disability rehabilitation, and major infectious diseases including AIDS, tuberculosis and malaria. We will also expand cooperation on traditional medicine.

We should increase our cooperation in science and technology, establish joint labs (or research centers), international technology transfer centers and maritime cooperation centers, promote sci-tech personnel exchanges, cooperate in tackling key sci-tech problems, and work together to improve sci-tech innovation capability.”

2 Two Novel Diagnostic Methods

The two diagnostic methods shown below - Retinal Micro Blood-Vessel Analysis and Chemical Breath Analysis - are unique in their sensitivity and early disease detection capability; these translate directly into better treatment options - and often also in the prevention of the disease altogether.

2.1 Fast and Bloodless Data Collection

The two methods allow fast and accurate patient data collection without drawing any blood and are well suited for screening of large numbers of people. Patients in risk groups can therefore be tested frequently, and even slight changes in the condition can be quickly detected.

2.2 Significant advantages for Mother and Child Diagnostics

2.2.1 Diagnostics during pregnancy

Pregnant women have special medical needs; regular check-ups are helpful. The two diagnostics methods described here allow frequent bloodless testing (without drawing blood) to monitor the metabolism and blood circulation of pregnant women. Both methods could allow the early detection of potential problems, as well as the subsequent frequent monitoring of any corrective measures. Both methods are completely painless; this will lower the threshold to visit the doctor regularly, as well as lowering the stress level during a doctor's visit considerably.

2.2.2 Diagnostics for Mother and Child

After birth, the continued normal development of mother and child can be frequently, quickly and inexpensively monitored; this will allow timely intervention if any pathological changes are detected. In pediatric medicine, where infants sometimes do not have enough blood to allow blood-based diagnostics, bloodless diagnostics can be a decisive factor for healthy development.

2.2.3 Real-time Breath Monitoring of Infant in Incubator

Babies which have to remain in an incubator after birth can be monitored contactlessly and continuously in real-time by Breath Analysis. This is an important advantage in modern neonatology, especially for newborns who require Intensive Care Unit (ICU) hospitalization.

2.2.4 Future Developments of the Two Novel Diagnostic Methods

In order to improve the accuracy and specificity of the two methods, an enlarged data base of correlated patient samples is helpful; to this end, we will invite interested Chinese medical research institutions to work with us in systematically building up this data base. The hardware for both technologies will be updated and upgraded periodically.

3 Micro Blood-Vessel Analysis of the Retina

3.1 Introduction

The vasculature of the eye and the heart share several common characteristics. The easily accessible vessels of the eye are therefore—to some extent—a window to the heart. There is interplay between cardiovascular functions and risk factors, and the occurrence and progression of many eye diseases. In particular, arteriovenous nipping, narrowing of retinal arteries, and the dilatation of retinal veins are important signs of increased cardiovascular risk. The pressure in the dilated veins is often markedly increased due to a dysregulation of venous outflow from the eye. Besides such morphological criteria, functional alterations might be even more relevant and may play an important role in future diagnostics.(J. Flammer)

3.2 The Science of Microvessel Analysis

The vasculature of the heart and retinal vessels share several common characteristics, and undergo similar changes during dysfunctional progression.^{[1][2][3]} The retina offers a convenient site for the imaging and detection of microvascular changes over time. The underlying science of the micro blood vessel analysis of the retina is based on the observation that cardio-vascular problems and diseases are first seen in the micro vessels and only after a relatively long time also show up in the large vessels; when a cardio-vascular problem is detected in the micro vessels of the retina, but not yet in the large vessels, it is a predictive indication of increased vascular risk, and there is usually ample time left to initiate corrective measures to lessen or completely avoid the break-out of the disease.

3.3 The History and Development of Microvessel Analysis

Micro Blood-Vessel Analysis has its roots in the USA and Europe, and has been further developed specifically in Germany and Switzerland.^[4] Statistical research started 20 years ago in the USA by Larry Hubbard (Atherosclerosis Risk in Communities (ARIC) Study), where protocols have been developed for nonmydriatic fundus photography and for evaluation of retinal vascular abnormalities. The broad study showed risk factors for heart attack and inflammation of blood vessels. The ARIC study, and also the Rotterdam study, were two of many studies focusing on Micro Blood-Vessel Analysis.^{[5] [6] [7] [8] [9] [10]}

About 25 years ago, Dr. Walthard Vilser initiated Dynamic Vessel Analysis (DVA) at Friedrich-Schiller-University at Jena; Dr. Vilser then started his own company and began to manufacture high-precision optical equipment. Prof. J.Flammer used Dr. Vilser's equipment to compare venous blood pressure vs. arterial blood pressure in the micro-vessels of the eye; he combined retinal DVA (Dynamic Vessel Analysis) and retinal Venal analysis, and for the first time recognized the vascular cause of glaucoma.^[2]

3.4 The Methods of Microvessel Analysis

Microvessel Analysis can be divided into two main segments: Static Micro Vessel Analysis (Figure 1), and Dynamic Micro Vessel Analysis (Figure 2).

Figure 1: Static Micro Vessel Analysis

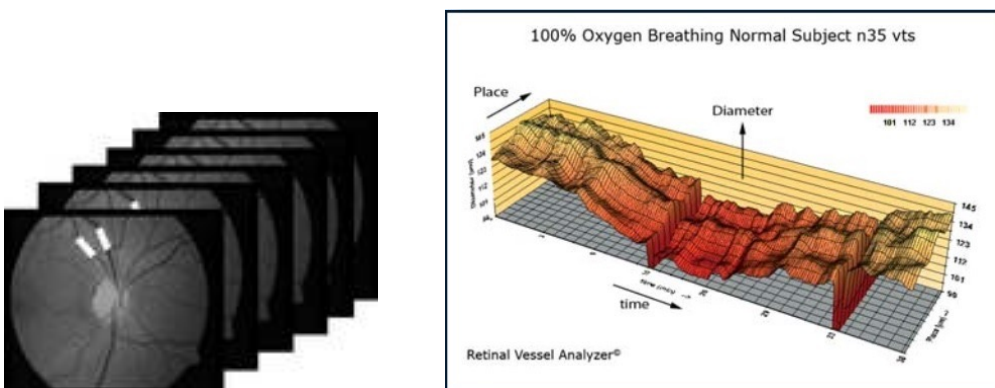

Figure 2: Dynamic Micro Vessel Analysis

Static Micro Vessel Analysis analyses the micro blood vessels of the retina statically, i.e. based on still images taken with a specialized camera, while Dynamic Micro Vessel Analysis analyses the micro blood vessels of the retina dynamically. In the dynamic vessel analysis, the vessel diameters are determined not only as a function of the place in an individual frame but in addition also continuously as a function of time in a live video. ^[11]

3.5 The Tools of Microvessel Analysis

The tools we propose are Imedos Retina Cameras: (Figure 3)

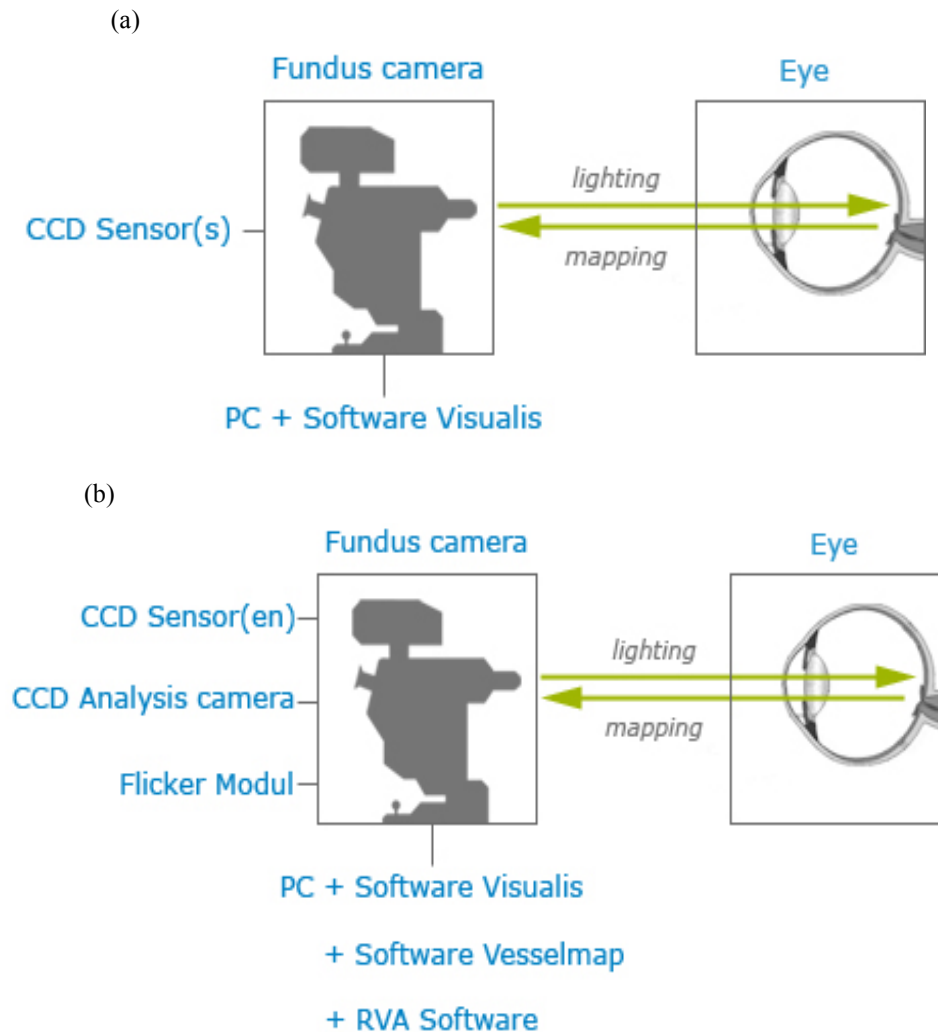

Figure 3: Main components of the (a) Static and (b) Dynamic Vessel Analysis systems

3.6 The Maturity of Microvessel Analysis

Both static and dynamic micro blood vessel analysis have reached a level of maturity which today allows early diagnostics of cardio-vascular problems – many years (5-15) before the problems actually break out. Early-generation equipment is already on the market, but it is still mainly used in ophthalmology; only a few research institutes have begun to use the equipment for general cardiovascular analysis and disease prevention.

4 Chemical Breath Analysis

4.1 Introduction

Breath analysis is the development of core technologies and methodologies for the safe, sensitive, fast and inexpensive analysis of exhaled breath.

Breath analysis is a highly promising diagnostic tool that allows rapid monitoring of biochemical parameters in real time and in a non-invasive way. It therefore has the potential to simplify diagnosis and monitoring of various diseases, and may at some point replace analyses that are currently performed on blood or urine samples.

4.2 The Science of Chemical Breath Analysis

Sample preparation for diagnostic purposes directly from the lung may be difficult. But exhaled breath is a unique window to the internal metabolism of the body, which can be analyzed with very high sensitivity and selectivity. Mass spectrometry allows the highest accuracy for the determination of chemical compounds with very little sample consumption. In the 1970s, Linus Pauling's study of exhaled breath using GC-MS (gas chromatography-mass spectrography) initiated the interest in breath analysis.^[15] The underlying science of Chemical Breath Analysis is based on the observation that in each exhaled breath of a human and animal is a wealth of information in the form of chemicals; these chemicals are found usually only in minute quantities. With new equipment based on well-proven mass spectrography – but specifically developed for this purpose - minute quantities of a given chemical can be detected.

4.3 The History of Chemical Breath Analysis

Detecting human disease by odor has a long history. From Hippocrates to Traditional Chinese Medicine to Lavoisier, and since ca. 10 years it is the object of intense studies at ETH Zurich.^[16]

There, the most sensitive instruments to date have been developed to analyze the chemical components of human breath.^{[17][18][19][20][21][22][23]} Many researchers and institutes are trying very hard to develop breath diagnosis technology with the support of the US, European Union, Israel and so on. In 2015, the team coming from Israel Institute of Technology declared that they had developed a breath diagnosis technology named NoNose which could detect 17 diseases.^[24]

4.4 The Methods of Chemical Breath Analysis

The breath of the patient/customer is exhaled into the entry tube of the aerosol ionizer under normal pressure; there the breath is ionized and passed on to the ultra-vacuum of the mass spectrograph. (Figure 4)

Figure 4: Schematic drawing of SESI ionizer

Figure 5: The aerosol ionizer interfaced with a mass spectrometer for the breath analysis

4.5 The Tools of Chemical Breath Analysis

The tools we propose to use for chemical breath analysis are aerosol ionizers by the ETH spin-off FIT. The Secondary Electro-Spray Ionization (SESI) manufactured by FIT uses an electrospray that produces a cloud of charging ions. These ions ionize the vapors that are in contact with the cloud. The charge transfer reactions are specific, very efficient, and very soft (no high energies involved). As a result, SESI enables:

- a very high ionization efficiency,
- soft ionization of polar species with no fragmentation, and

- an instantaneous response.

4.6 The Maturity of Chemical Breath Analysis

Chemical Breath Analysis is still in its early stage of development. The equipment required to find minute quantities of a given molecule in the human breath exists today but is still very expensive and complex. Some problems still need to be solved, like the problem of the heavy molecules in the exhaled breath sticking to the instrument walls. The newly developed hardware can overcome the problem of ionizing aerosols and prepare them in a way suitable for most standard mass spectrographs; to analyze the vast amount of data resulting from each breath submitted to the ionizer, specific pattern recognition software was developed.

6.2.1 Micro Vessel Analysis

Title: The Relation of Retinal Vessel Caliber to the Incidence and Progression of Diabetic Retinopathy XIX: The Wisconsin Epidemiologic Study of Diabetic Retinopathy
Date: 2004
Authors: Ronald Klein, MD, MPH; Barbara E. K. Klein, MD; Scot E. Moss, MA

Abstract:

Objective: To describe the relation of retinal arteriolar and venular caliber to the incidence and progression of diabetic retinopathy in people with type1 diabetes mellitus.

Design: Incidence findings in a population-based study of diabetic retinopathy in Wisconsin. Participants included 996 persons diagnosed as having diabetes mellitus before 30 years of age who took insulin and underwent the baseline examination, 891 in the 4-year follow-up, 765 in the 10-year follow-up, and 634 in the 14-year follow-up. Retinal photographs of 7 standard fields were taken at all examinations. Computer-assisted grading was performed from a digitized image of field 1 to determine the average diameter of retinal arterioles and venules and their ratio. Main outcome measures included incidence and progression of retinopathy, incidence of proliferative retinopathy, and macular edema.

Results: While adjusting for other factors, larger arteriolar (relative risk[RR] for the fourth vs first quartile range, 2.04; 95% confidence interval[CI], 1.20-3.47; test of trend, $P = .008$) and venular diameters (RR, 2.33; 95% CI, 1.37-3.95; test of trend, $P = .005$) were associated with greater 4-year progression of retinopathy. Larger venular diameters (RR, 4.28; 95% CI, 1.50-12.19; test of trend, $P = .006$) but not arteriolar diameters were associated with greater 4-year incidence of proliferative retinopathy. In multivariable analyses, arteriolar and venular calibers were not associated with the 4-year incidence of retinopathy. While adjusting for other factors, arteriolar and venular calibers were not associated with incidence of macular edema at 4 years. There were few associations of arteriolar or venular caliber with the 10- or 14-year incidence or the progression of retinopathy.

Conclusions: Larger arteriolar and venular caliber, independent of retinopathy severity level, is related to the progression of retinopathy, and larger venular caliber is associated with the 4-year incidence of proliferative retinopathy. Caliber of retinal vessels is not associated with incident retinopathy. These data suggest a quantitative measure of retinal vascular caliber provides additional information regarding risk for progression of retinopathy.

Title: Retinal Vessel Diameters and Risk of Hypertension
Date: 2006

Authors: M. Kamran Ikram, Jacqueline C.M. Witteman, Johannes R. Vingerling, Monique M.B. Breteler, Albert Hofman and Paulus T.V.M. de Jong

Abstract: Generalized retinal arteriolar narrowing is an important sign of systemic hypertension, and a lower arteriolar: venular diameter ratio predicts the risk of hypertension. We investigated whether this association was based on arteriolar or venular diameters or both. This study was based on the prospective population-based Rotterdam Study (1990–1993) and included 1900 participants (55 years of age) of whom 739 persons had normal blood pressure (systolic 120 mm Hg and diastolic 80 mm Hg) and 1161 prehypertension (systolic 120 to 139 mm Hg or diastolic 80 to 89 mm Hg). For each participant, retinal arteriolar and venular diameters were measured on digitized images of 1 eye. After a mean follow-up of 6.6 years, 808 persons developed hypertension, defined as either systolic blood pressure 140 mm Hg or diastolic blood pressure 90 mm Hg or use of antihypertensive medication. Adjusted for age, gender, follow-up time, body mass index, smoking, diabetes mellitus, total and high-density lipoprotein cholesterol, C-reactive protein, and intima-media thickness, arteriolar narrowing was associated with an increased risk of hypertension (odds ratio per SD: 1.38; 95% CI, 1.23 to 1.55); for venular narrowing this was less striking (OR: 1.17; 95% CI, 1.04 to 1.32). Each SD decrease in the arteriolar: venular diameter ratio significantly increased the risk of hypertension by 24%. To examine the effect of baseline blood pressure, we stratified persons into those with “normal blood pressure” or “prehypertension.” Within these strata, arteriolar narrowing was still related to incident hypertension. These data show that both retinal arteriolar and venular narrowing may precede the development of systemic hypertension. (Hypertension. 2006; 47:189-194.)

Breteler, Albert Hofman and Paulus T.V.M. de Jong Hypertension. 2006; 47:189-194; originally published online December 27, 2005; DOI: 10.1161/01.HYP.0000199104.61945.33

Title: Retinal vessel diameter and cardiovascular mortality: pooled data analysis from two older populations

Date: 2007

Authors: Jie Jin Wang, Gerald Liew, Ronald Klein, Elena Ročtchina, Michael D. Knudtson, Barbara E.K. Klein, Tien Yin Wong, George Burlutsky, and Paul Mitchell

Abstract:

Aims: The retinal microvasculature may reflect pre-clinical changes in the cerebral and coronary micro-circulations. We assessed whether smaller retinal arterioles and larger venules predicted coronary heart disease (CHD)- and stroke-mortality.

Methods and results: We pooled data from the Beaver Dam Eye Study (n 1/4 4926, aged 43–86) and the Blue Mountains Eye Study (n 1/4 3654, aged 49–97). Retinal vessel diameters were measured from digitized retinal photographs. Change point models were used to assess and document the existence of threshold effects. We defined smaller arterioles as diameters within the narrowest quintile and larger venules as diameters within the widest quintile, with other quintiles as the reference. Of 8550 participants, 7494 (88%) with complete data were included, of whom 653 died from CHD and 299 from stroke over 10–12 years follow-up. After multivariable adjustment, each standard deviation (SD) increase in arteriolar diameter, or SD decrease in venular diameter, was not found to be significantly associated with either CHD-mortality or stroke-mortality. However, smaller arterioles [hazard ratio (HR) 1.34, 95% confidence interval (CI) 1.11–1.62] and larger venules (HR 1.24, CI 1.02–1.52), predicted increased risk of CHD-mortality. These associations were mainly evident among persons aged 43–69 (smaller arterioles: HR 1.70, CI 1.27–2.28; larger venules: HR 1.41, CI 1.06–1.89). Smaller arterioles (HR 1.64, CI 1.00–2.67) and larger venules (HR 1.53, CI 0.94–2.47) were also associated with an increased risk of stroke-mortality among persons aged 43–69.

Conclusion: Retinal vessel diameter may predict risk of CHD and stroke deaths in middle-aged persons.

Title: Use of the retinal vessel analyzer in ocular blood flow research

Date: 2009

Authors: Garhofer, G., Bek, T., Boehm, A. G., Gherghel, D., Grunwald, J., Jeppesen, P., ... & Nagel, E.

Abstract: The present article describes a standard instrument for the continuous online determination of retinal vessel diameters, the commercially available retinal vessel analyzer. This report is intended to provide informed guidelines for measuring ocular blood flow with this system. The report describes the principles underlying the method and the instruments currently available, and discusses clinical protocol and the specific parameters measured by the system. Unresolved questions and the possible limitations of the technique are also discussed.

Title: Retinal Vascular Caliber: Systemic, Environmental, and Genetic Associations

Date: 2009

Authors: Cong Sun, MD, MPH, Jie Jin Wang, MMed, PhD, David A. Mackey, MD, Tien Y. Wong, MD, PhD

Abstract: Quantitative studies of retinal vascular caliber using new computer-assisted retinal imaging systems have allowed physicians and researchers to understand the influence of systemic, environmental, and genetic factors on retinal vascular caliber. Retinal vascular caliber changes reflect cumulative response to aging, cardiovascular risk factors, inflammation, nitric oxide-dependent endothelial dysfunction, and other processes. Recent epidemiological studies have shown that changes in retinal arteriolar and venular caliber size may reflect the differential effects of a range of systemic, environmental, and genetic risk factors. Narrower retinal arteriolar caliber and smaller arteriovenous ratio are associated with older age; higher levels of past, current, and future blood pressure and obesity; and predict the incidence of diabetes and coronary heart disease. Wider retinal venular caliber, in contrast, is associated with younger age; impaired fasting glucose and diabetes; dyslipidemia; obesity; systemic marker of inflammation, endothelial dysfunction, and cigarette smoking; and predicts the risk of stroke and coronary heart disease. New data from family and twin studies indicate a significant genetic contribution to retinal vascular caliber, an area that is under investigation. Elucidating the complete range of systemic, environmental, and genetic factors linked with retinal vascular caliber changes may provide critical insight into the etiology, pathogenesis, and natural history of early vascular disease not only in the eye but elsewhere in the body.

Title: Meta-analysis: Retinal Vessel Caliber and Risk for Coronary Heart Disease

Date: 2009

Authors: McGeechan K, Liew G, Macaskill P, Irwig L, Klein R, Klein BE, et al.

Abstract:

Background:

Retinal vessel caliber may be a novel marker of coronary heart disease (CHD) risk. However, the sex-specific effect, magnitude of association, and effect independent of traditional CHD disease risk factors remain unclear.

Purpose:

To determine the association between retinal vessel caliber and risk for CHD.

Data Sources:

Relevant studies in any language identified through MEDLINE (1950 to June 2009) and EMBASE (1950 to June 2009) databases.

Study Selection:

Studies were included if they examined a general population, measured retinal vessel caliber from retinal photographs, and documented CHD risk factors and incident CHD events.

Data Extraction:

6 population-based prospective cohort studies provided data for individual participant meta-analysis.

Data Synthesis:

Proportional hazards models, adjusted for traditional CHD risk factors, were constructed for retinal vessel caliber and

incident CHD in women and men. Among 22 159 participants who were free of CHD and followed for 5 to 14 years, 2219 (10.0%) incident CHD events occurred. Retinal vessel caliber changes (wider venules and narrower arterioles) were each associated with an increased risk for CHD in women (pooled multivariable-adjusted hazard ratios, 1.16 [95% CI, 1.06 to 1.26] per 20- μ m increase in venular caliber and 1.17 [CI, 1.07 to 1.28] per 20- μ m decrease in arteriolar caliber) but not in men (1.02 [CI, 0.94 to 1.10] per 20- μ m increase in venular caliber and 1.02 [CI, 0.95 to 1.10] per 20- μ m decrease in arteriolar caliber). Women without hypertension or diabetes had higher hazard ratios.

Limitation:

Error in the measurement of retinal vessel caliber and Framingham variables was not taken into account.

Conclusion:

Retinal vessel caliber changes were independently associated with an increased risk for CHD events in women.

Title: Retinal Vascular Signs: A Window to the Heart?

Date: 2011

Authors: Gerald Liew, Jie Jin Wang

Abstract: There is increasing recognition that coronary microvascular dysfunction also plays an important role in coronary heart disease. Little is known about this aspect of coronary heart disease due to difficulties in studying the coronary microcirculation directly. The retina is a unique site where the microcirculation can be imaged directly, providing an opportunity to study in vivo the structure and pathology of the human circulation and the possibility of detecting changes in microvasculature relating to the development of cardiovascular disease. This review covers the recent progress in research linking retinal vascular signs to coronary heart disease, and finds accumulating evidence that retinal vascular signs may provide a window into the health of the coronary microvasculature. The most widely studied signs, arteriolar narrowing, and more recently, venular dilation, are likely associated with increased risk of coronary heart disease in women, independent of traditional risk factors. Attempts to improve coronary heart disease risk prediction by incorporating retinal vessel caliber size into risk prediction scores complementing traditional algorithms such as the Framingham risk scores have so far been disappointing. Research is ongoing into the predictive utility of other retinal vascular signs. Retinal photography provides long-lasting records that enable monitoring of longitudinal changes in these retinal signs and vascular health.

Title: Exercise-induced alterations of retinal vessel diameters and cardiovascular risk reduction in obesity.

Date: 2011

Authors: Hanssen H1, Nickel T, Drexel V, Hertel G, Emslander I, Sisic Z, Lorang D, Schuster T, Kotliar KE, Pressler A, Schmidt-Trucksäss A, Weis M, Halle M

Abstract:

Background: The retinal microcirculation is affected early in the process of atherosclerosis and retinal vessel caliber is an emerging cardiovascular risk factor. Obesity is associated with vascular dysfunction. Here, we investigate the effect of regular exercise on retinal vessel diameters in lean and obese runners. We analyze a possible link to alterations of the nitric oxide (NO)-asymmetric dimethylarginine (ADMA) pathway.

Methods: Retinal vessel diameters were assessed by means of a static vessel analyzer (SVA-T) in 15 obese athletes (OA), 14 lean amateur athletes (AA) and 17 lean elite athletes (EA) following a 10-week training program. ADMA serum levels were detected by ELISA and dimethylarginine dimethylaminohydrolase (DDAH) -1/-2 mRNA-expression in peripheral mononuclear cells (PBMC) was analyzed by real time PCR.

Results: At baseline, the mean (\pm SD) arteriolar to venular diameter ratio (AVR) was impaired in obese (OA: 0.81 \pm 0.05)

compared to lean subjects (AA: 0.87 ± 0.07 ; EA: 0.94 ± 0.05). The individual fitness levels correlated with AVR ($\rho = +0.66$; $P < 0.001$) and the training program improved AVR in all groups ($P < 0.001$), normalizing AVR in the obese (OA: 0.86 ± 0.1). A training-induced arteriolar dilatation was found in OA ($P = 0.01$), which was accompanied by a significant decrease of ADMA levels (0.56 ± 0.12 – $0.46 \pm 0.12 \mu\text{mol/l}$ (-1); $P < 0.028$). DDAH-1 mRNA levels in PBMC increased in all groups ($P < 0.01$).

Conclusions: Cardiovascular fitness and body composition affect retinal vessel diameters. Regular exercise reverses the subclinical impairment of the retinal microvasculature in obesity by inducing retinal arteriolar dilatation. The NO/ADMA pathway may play a key role in the training-induced improvement of microvascular function, which has the potential to counteract progression of small vessel disease.

Title: Retinal Vessel Caliber and Lifelong Neuropsychological Functioning: Retinal Imaging as an Investigative Tool for Cognitive Epidemiology

Date: 2013

Authors: Idan Shalev, Terrie E. Moffitt, Tien Y. Wong, Madeline H. Meier, Renate M. Houts, Jie Ding, Carol Y. Cheung, M. Kamran Ikram, Avshalom Caspi, and Richie Poulton

Abstracts: Why do more intelligent people live healthier and longer lives? One possibility is that intelligence tests assess health of the brain, but psychological science has lacked technology to evaluate this hypothesis. Digital retinal imaging, a new, noninvasive method to visualize microcirculation in the eye, may reflect vascular conditions in the brain. We studied the association between retinal vessel caliber and neuropsychological functioning in the representative Dunedin birth cohort. Wider venular caliber was associated with poorer neuropsychological functioning at midlife, independently of potentially confounding factors. This association was not limited to any specific test domain and extended to informants' reports of cohort members' cognitive difficulties in everyday life. Moreover, wider venular caliber was associated with lower childhood IQ tested 25 years earlier. The findings indicate that retinal venular caliber may be an indicator of neuropsychological health years before the onset of dementing diseases and suggest that digital retinal imaging may be a useful investigative tool for psychological science.

Title: Blood flow in glaucoma

Date: 2005

Author: Matthias C Grieshaber, Josef Flammer

Abstract:

Purpose of review: Glaucoma, one of the leading causes of blindness in the world, is characterized by progressive visual field loss and distinctive excavation of the optic nerve head. Although elevated intraocular pressure is the major risk factor, there is increasing evidence that the pathogenesis of glaucoma is also linked to altered ocular blood flow. This review summarizes the recent publications relevant to blood flow in glaucoma.

Recent findings: Several studies indicate that a perfusion instability, rather than a steady reduction of ocular blood flow, might contribute to glaucomatous optic neuropathy. The main cause of the instability is a disturbed autoregulation in the context of a general vascular dysregulation. The underlying mechanism of such a vascular dysregulation is not known. A dysfunction of both the autonomic nervous system and vascular endothelial cells is discussed.

Summary: The mechanical and vascular theories are not mutually exclusive; on the contrary, a vascular dysregulation increases the susceptibility to intraocular pressure. Therapeutically, therefore, both an intraocular pressure reduction and an improvement of the ocular blood flow might be considered.

Title: What Is the Link Between Vascular Dysregulation and Glaucoma?

Date: 2007

Author: Matthias C. Grieshaber, MD, FEBO, Maneli Mozaffarieh, MD, Josef Flammer, MD

Abstract: The need of blood flow to different organs varies rapidly over time which is why there is sophisticated local regulation of blood flow. The term dysregulation simply means that blood flow is not properly adapted to this need. Dysregulative mechanisms can lead to an over- or under perfusion. A steady over perfusion may be less critical for long-term damage. A constant under perfusion, however, can lead to some tissue atrophy or in extreme situations to infarction. Unstable perfusion (under perfusion followed by reperfusion) leads to oxidative stress. There are a number of causes that lead to local or systemic vascular dysregulation. Systemic dysregulation can be primary or secondary of nature. A secondary dysregulation is due to other autoimmune diseases such as rheumatoid arthritis, giant cell arteritis, systemic lupus erythematoses, multiple sclerosis, colitis ulcerosa, or Crohns disease. Patients with a secondary vascular dysregulation normally have a high level of circulating endothelin-1 (ET-1). This increased level of ET-1 leads to a reduction of blood flow both in the choroid and the optic nerve head but has little influence on autoregulation. In contrast, primary vascular dysregulation has little influence on baseline ocular blood flow but interferes with autoregulation. This, in turn, leads to unstable oxygen supply, which seems to be a relevant component in the pathogenesis of glaucomatous optic neuropathy.

Title: The primary vascular dysregulation syndrome: implications for eye diseases

Date: 2013

Author: Flammer, J., Konieczka, K., & Flammer, A. J.

Abstract: Vascular dysregulation refers to the regulation of blood flow that is not adapted to the needs of the respective tissue. We distinguish primary vascular dysregulation (PVD, formerly called vasospastic syndrome) and secondary vascular dysregulation (SVD). Subjects with PVD tend to have cold extremities, low blood pressure, reduced feeling of thirst, altered drug sensitivity, increased pain sensitivity, prolonged sleep onset time, altered gene expression in the lymphocytes, signs of oxidative stress, slightly increased endothelin-1 plasma level, low body mass index and often diffuse and fluctuating visual field defects. Coldness, emotional or mechanical stress and starving can provoke symptoms. Virtually all organs, particularly the eye, can be involved. In subjects with PVD, retinal vessels are stiffer and more irregular, and both neurovascular coupling and autoregulation capacity are reduced while retinal venous pressure is often increased. Subjects with PVD have increased risk for normal-tension glaucoma, optic nerve compartment syndrome, central serous choroidopathy, Susac syndrome, retinal artery and vein occlusions and anterior ischaemic neuropathy without atherosclerosis. Further characteristics are their weaker blood- brain and blood-retinal barriers and the higher prevalence of optic disc haemorrhages and activated astrocytes. Subjects with PVD tend to suffer more often from tinnitus, muscle cramps, migraine with aura and silent myocardial ischaemic and are at greater risk for altitude sickness. While the main cause of vascular dysregulation is vascular endotheliopathy, dysfunction of the autonomic nervous system is also involved. In contrast, SVD occurs in the context of other diseases such as multiple sclerosis, retrobulbar neuritis, rheumatoid arthritis, fibromyalgia and giant cell arteritis. Taking into consideration the high prevalence of PVD in the population and potentially linked pathologies, in the current article, the authors provide recommendations on how to effectively promote the field in order to create innovative diagnostic tools to predict the pathology and develop more efficient treatment approaches tailored to the person.

Title: The eye and the heart

Date: 2013

Author: Flammer, J; Konieczka, K; Bruno, R M; Viridis, A; Flammer, A J; Taddei, S

Abstract: The vasculature of the eye and the heart share several common characteristics. The easily accessible vessels of the eye are therefore to some extent a window to the heart. There is interplay between cardiovascular functions and risk factors and the occurrence and progression of many eye diseases. In particular, arteriovenous nicking, narrowing of retinal arteries, and the dilatation of retinal veins are important signs of increased cardiovascular risk. The pressure in the dilated veins is often markedly increased due to a dysregulation of venous outflow from the eye. Besides such morphological criteria, functional alterations might be even more relevant and may play an important role in future diagnostics. Via neurovascular coupling, flickering light dilates capillaries and small arterioles, thus inducing endothelium-dependent, flow-mediated dilation of larger retinal vessels. Risk factors for arteriosclerosis, such as dyslipidaemia, diabetes, or systemic hypertension, are also risk factors for eye diseases such as retinal arterial or retinal vein occlusions, cataracts, age-related macular degeneration, and increases in intraocular pressure (IOP). Functional alterations of blood flow are particularly relevant to the eye. The primary vascular dysregulation syndrome (PVD), which often includes systemic hypotension, is associated with disturbed autoregulation of ocular blood flow (OBF). Fluctuation of IOP on a high level or blood pressure on a low-level lead to instable OBF and oxygen supply and therefore to oxidative stress, which is particularly involved in the pathogenesis of glaucomatous neuropathy. Vascular dysregulation also leads to a barrier dysfunction and thereby to small retinal haemorrhages.

Title: Diagnosis and Classification of Diseases from 1404 Subjects via Pattern Analysis of Exhaled Molecules

Date: 2015

Author: Morad K. Nakhleh,† Haitham Amal, Raneen Jeries,† Yoav Y. Broza

Abstract: We report on an artificially intelligent nanoarray based on molecularly modified gold nanoparticles and a random network of single-walled carbon nanotubes for noninvasive diagnosis and classification of a number of diseases from exhaled breath. The performance of this artificially intelligent nanoarray was clinically assessed on breath samples collected from 1404 subjects having one of 17 different disease conditions included in the study or having no evidence of any disease (healthy controls). Blind experiments showed that 86% accuracy could be achieved with the artificially intelligent nanoarray, allowing both detection and discrimination between the different disease conditions examined. Analysis of the artificially intelligent nanoarray also showed that each disease has its own unique breathprint, and that the presence of one disease would not screen out others. Cluster analysis showed a reasonable classification power of diseases from the same categories. The effect of confounding clinical and environmental factors on the performance of the nanoarray did not significantly alter the obtained results. The diagnosis and classification power of the nanoarray was also validated by an independent analytical technique, i.e., gas chromatography linked with mass spectrometry. This analysis found that 13 exhaled chemical species, called volatile organic compounds, are associated with certain diseases, and the composition of this assembly of volatile organic compounds differs from one disease to another. Overall, these findings could contribute to one of the most important criteria for successful health intervention in the modern era, viz. easy-to-use, inexpensive (affordable), and miniaturized tools that could also be used for personalized screening, diagnosis, and follow-up of a number of diseases, which can clearly be extended by further development.

Title: Human breath analysis may support the existence of individual metabolic phenotypes

Date: 2013

Author: Martinez-Lozano Sinues, Pablo; Kohler, Malcolm; Zenobi, Renato

Abstract: The metabolic phenotype varies widely due to external factors such as diet and gut microbiome composition, among others. Despite these temporal fluctuations, urine metabolite profiling studies have suggested that there are highly

individual phenotypes that persist over extended periods of time. This hypothesis was tested by analyzing the exhaled breath of a group of subjects during nine days by mass spectrometry. Consistent with previous metabolomics studies based on urine, we conclude that individual signatures of breath composition exist. The confirmation of the existence of stable and specific breath prints may contribute to strengthen the inclusion of breath as a bio fluid of choice in metabolomics studies. In addition, the fact that the method is rapid and totally non-invasive, yet individualized profiles can be tracked, makes it an appealing approach.

Published: Martinez-Lozano Sinues P, Kohler M, Zenobi R., Human breath analysis may support the existence of individual metabolic phenotypes. (2013), Plos One, 8(4), DOI: 10.1371/journal.pone.0059909;

Title: Circadian variation of the human metabolome captured by real-time breath analysis

Date: 2014

Author: highlight remove highlight from please wait search word highlight Martinez-Lozano Sinues, Pablo; Tarokh, Leila; Li, Xue; Kohler, Malcolm; Brown, Steven A; Zenobi, Renato; Dallmann, Robert

Abstract: Circadian clocks play a significant role in the correct timing of physiological metabolism, and clock disruption might lead to pathological changes of metabolism. One interesting method to assess the current state of metabolism is metabolomics. Metabolomics tries to capture the entirety of small molecules, i.e. the building blocks of metabolism, in a given matrix, such as blood, saliva or urine. Using mass spectrometric approaches, we and others have shown that a significant portion of the human metabolome in saliva and blood exhibits circadian modulation; independent of food intake or sleep/wake rhythms. Recent advances in mass spectrometry techniques have introduced completely non-invasive breath printing; a method to instantaneously assess small metabolites in human breath. In this proof-of-principle study, we extend these findings about the impact of circadian clocks on metabolomics to exhaled breath. As previously established, our method allows for real-time analysis of a rich matrix during frequent non-invasive sampling. We sampled the breath of three healthy, non-smoking human volunteers in hourly intervals for 24 hours during total sleep deprivation, and found 111 features in the breath of all individuals, 36-49% of which showed significant circadian variation in at least one individual. Our data suggest that real-time mass spectrometric "breath printing" has high potential to become a useful tool to understand circadian metabolism, and develop new biomarkers to easily and in real-time assess circadian clock phase and function in experimental and clinical settings.

Title: Breath analysis in real time by mass spectrometry in chronic obstructive pulmonary disease

Date: 2014

Author: Martinez-Lozano Sinues, Pablo; Meier, Lukas; Berchtold, Christian; Ivanov, Mark; Sievi, Noriane; Camen, Giovanni; Kohler, Malcolm; Zenobi, Renato

Abstract: It has been suggested that exhaled breath contains relevant information on health status. OBJECTIVES: We hypothesized that a novel mass spectrometry (MS) technique to analyze breath in real time could be useful to differentiate breath prints from chronic obstructive pulmonary disease (COPD) patients and controls (smokers and nonsmokers). METHODS: We studied 61 participants including 25 COPD patients [Global Initiative for Obstructive Lung Disease (GOLD) stages I-IV], 25 nonsmoking controls and 11 smoking controls. We analyzed their breath by MS in real time. Raw mass spectra were then processed and statistically analyzed. RESULTS: A panel of discriminating mass-spectral features was identified for COPD (all stages; n = 25) versus healthy nonsmokers (n = 25), COPD (all stages; n = 25) versus healthy smokers (n = 11) and mild COPD (GOLD stages I/II; n = 13) versus severe COPD (GOLD stages III/IV; n = 12). A blind classification (i.e. leave-one-out cross validation) resulted in 96% sensitivity and 72.7% specificity (COPD vs. smoking controls), 88% sensitivity and 92% specificity (COPD vs. nonsmoking controls) and 92.3% sensitivity and 83.3% specificity (GOLD I/II vs. GOLD III/IV). Acetone and indole were identified as two of the discriminating exhaled molecules. CONCLUSIONS: We conclude that real-time MS may be a useful technique to analyze and characterize the metabolome of exhaled breath. The acquisition of breath prints in a rapid manner may be valuable to support COPD diagnosis and to gain insight into the disease.

Title: Identification of 2-Alkenals, 4-Hydroxy-2-alkenals, and 4-Hydroxy-2,6-alkadienals in Exhaled Breath Condensate by UHPLC-HRMS and in Breath by Real-Time HRMS

Date: 03,03,2015

Author: Diego García-Gómez, Pablo Martínez-Lozano Sinues, César Barrios-Collado, Guillermo Vidal-de-Miguel, Martin Gaugg, and Renato Zenobi

Abstract: In recent years, breath analysis in real time has become a noninvasive alternative for the diagnosis of diseases and for molecular fingerprinting of exhaled breath. However, the techniques used lack the capabilities for proper identification of the compounds found in the exhalome. Here, we report the use of UHPLC-HRMS as a tool for the identification of several aldehydes (2-alkenals, 4-hydroxy-2-alkenals, and 4-hydroxy-2,6-alkadienals), biomarkers of lipid peroxidation, in exhaled breath condensate of three healthy subjects (N = 3). Some of the aldehydes studied have never been identified before. Their robust identification is based on retention times, on the generation of fragmentation trees from tandem mass spectra, and on the comparison of these parameters with standards. We also show that the identified compounds can be analyzed and confirmed by MS/MS in breath in real time and, therefore, they could be used as biomarkers for the rapid and noninvasive diagnosis of related diseases.

Title: Drug pharmacokinetics determined by real-time analysis of mouse breath

Date: 2015

Author: Li, Xue ; Martínez-Lozano Sinues, Pablo ; Dallmann, Robert ; Bregy, Lukas ; Hollmén, Maija ; Proulx, Steven ; Brown, Steven A ; Detmar, Michael ; Kohler, Malcolm ; Zenobi, Renato

Abstract: Noninvasive, real-time pharmacokinetic (PK) monitoring of ketamine, propofol, and valproic acid, and their metabolites was achieved in mice, using secondary electrospray ionization and high-resolution mass spectrometry. The PK profile of a drug influences its efficacy and toxicity because it determines exposure time and levels. The antidepressant and anaesthetic ketamine (Ket) and four Ket metabolites were studied in detail and their PK was simultaneously determined following application of different sub-anaesthetic doses of Ket. Bioavailability after oral administration vs. intraperitoneal injection was also investigated. In contrast to conventional studies that require many animals to be sacrificed even for low-resolution PK curves, this novel approach yields real-time PK curves with a hitherto unmatched time resolution (10 s), and none of the animals has to be sacrificed. This thus represents a major step forward not only in animal welfare, but also major cost and time savings.

Title: Real-Time High-Resolution Tandem Mass Spectrometry Identifies Furan Derivatives in Exhaled Breath

Date: 07,07,2015

Author: Diego García-Gómez, Lukas Bregy, César Barrios-Collado, Guillermo Vidal-de-Miguel, and Renato Zenobi

Abstract: The identification of chemical compounds in exhaled human breath is promising in the search for new biomarkers of diseases. However, the analytical techniques used nowadays are not capable of achieving a robust identification, especially in real-time analysis. In this work, we show that real-time high-resolution tandem mass spectrometry (HRMS/MS) is suitable for the identification of biomarkers in exhaled breath. Using this approach, we identified a number of furan derivatives, compounds found in the exhalome whose nature and origin are not yet clearly understood. It is also shown that the combination of HRMS/MS with UHPLC allowed not only the identification of the furan derivatives but also the proper separation of their isomeric forms.

Published: García-Gómez D, Bregy L, Barrios-Collado C, Vidal-de-Miguel G, Zenobi R, Real-Time High-Resolution Tandem Mass Spectrometry Identifies Furan Derivatives in Exhaled Breath, (2015), Analytical Chemistry, 87(13):6919-6924; DOI: 10.1021/acs.analchem.5b01509

Title: Expanding metabolite coverage of real-time breath analysis by coupling a universal secondary electrospray ionization source and high resolution mass spectrometry - a pilot study on tobacco smokers

Date: 2016

Author: Gaugg, Martin Thomas; Gomez, Diego Garcia ; Barrios-Collado, Cesar ; Vidal-de-Miguel, Guillermo ; Kohler, Malcolm ; Zenobi, Renato ; Martinez-Lozano Sinues, Pablo

Abstract: Online breath analysis is an attractive approach to track exhaled compounds without sample preparation. Current commercially available real-time breath analysis platforms require the purchase of a full mass spectrometer. Here we present an ion source compatible with virtually any preexisting atmospheric pressure ionization mass spectrometer that allows real-time analysis of breath. We illustrate the capabilities of such technological development by upgrading an orbitrap mass spectrometer. As a result, we detected compounds in exhaled breath between 70 and 900 Da, with a mass accuracy of typically <1 ppm; resolutions between $m/\Delta m$ 22,000 and 70,000 and fragmentation capabilities. The setup was tested in a pilot study, comparing the breath of smokers (n=9) and non-smokers (n=10). Exogenous compounds associated to smoking, as well as endogenous metabolites suggesting increased oxidative stress in smokers, were detected and in some cases identified unambiguously. Most of these compounds correlated significantly with smoking frequency and allowed accurate discrimination of smokers and non-smokers.
